

Toxic Comment Classification

Aruna Neervannan

Abstract

In this project I have built multi-headed model that is capable of detecting different types of toxicity like threats, obscenity, insults, and identity-based hate better than Perspectives current models. I am using the kaggle dataset which has comments from Wikipedias talk page edits. KeywordsToxic Comment, Neural Network, CNN, Bi-directional LSTM

I. INTRODUCTION

A flood of content is produced on a daily basis throughout the Internet, on social media sites etc from the online interaction between users. While this situation contributes significantly to the quality of human life, unfortunately it involves enormous dangers, since online texts with high toxicity can cause personal attacks, online harassment and bullying behaviors. Discussing things you care about can be difficult.

II. PURPOSE

The purpose of this project is to build models that best classifies the comments into the following categories: toxic, severe_toxic, obscene, threat, insult, identify_hate.

A. *Motivation*

Traditionally Recurrent Neural Networks are best known to work with text data and Convolutional Neural Networks with image processing. Recently, Convolutional Neural Networks (CNN) are being applied to text classification or natural language processing both to distributed as to discrete embedding of words [1], without using syntactic or semantic knowledge of a language [3]. Also, a recurrent CNN model was proposed recently for text classification without human-designed features [2] by succeeding to outperform both the CNN model as well as other well-established classifiers.

III. DATA

A. *Source*

Data for this project are a large number of Wikipedia comments that is part of the Kaggle dataset.

B. *Variables*

The dataset has the commentID, comment and the toxicity. The comments have been labeled by human raters for toxic behavior. The types of toxicity:

- 1) toxic
- 2) severe_toxic
- 3) obscene
- 4) threat
- 5) insult
- 6) identity_hate

C. Test-Train Data Split

Kaggle Dataset did have a label test and train data set.

D. Preprocessing

Keras provides the Tokenizer class for preparing text documents for deep learning. The Tokenizer must be constructed and then fit on either raw text documents or integer encoded text documents. The tokenized input sentences are then padded to a max length of 170.

IV. EMBEDDINGS

A word embedding is an approach to provide a dense vector representation of words that capture something about their meaning. It turns text into numbers and helps building a low-dimensional vector representation from corpus of text, which preserves the contextual similarity of words.

Word embeddings are an improvement over simpler bag-of-words model word encoding schemes like word counts and frequencies that result in large and sparse vectors (mostly 0 values) that describe documents but not the meaning of the words.

Word embeddings work by using an algorithm to train a set of fixed-length dense and continuous-valued vectors based on a large corpus of text. Each word is represented by a point in the embedding space and these points are learned and moved around based on the words that surround the target word.

It is defining a word by the company that it keeps that allows the word embedding to learn something about the meaning of words. The vector space representation of the words provides a projection where words with similar meanings are locally clustered within the space.

The use of word embeddings over other text representations is one of the key methods that has led to breakthrough performance with deep neural networks on problems like machine translation.

For this project Stanford GloVe embeddings were used: Common Crawl (840B tokens, 2.2M vocab, cased, 300d vectors, 2.03 GB download): glove.840B.300d.zip

V. MODELS

Logistic Regression

Implemented logistic regression using SciPy libraries and calculated the Cross-validation scores for each of the comment classifications.

Formally, the model logistic regression model is that

$$\log\left(\frac{p(x)}{1-p(x)}\right) = \beta_0 + x.\beta$$

Solving for p, this gives

$$p(x; \beta_0, \beta) = \frac{e^{\beta_0 + x.\beta}}{1 + e^{\beta_0 + x.\beta}} = \frac{1}{1 + e^{-(\beta_0 + x.\beta)}}$$

To minimize the mis-classification rate, we should predict $Y = 1$ when $p \geq 0.5$ and $Y = 0$ when $p < 0.5$. This means guessing 1 whenever $\beta_0 + x.\beta$ is non-negative, and 0 otherwise. So logistic regression gives us a linear classifier

Convolutional Neural Networks

This section I implemented the CNN model from Convolutional Neural Networks for Sentence Classification [2]. I used three convolutional layers, with filter size width 128, dense vector dimension 300. The filters width is equal to the vector dimension while their height was 3, 4 and 5, for each convolutional layer respectively. After each convolutional layer a max-over-time pooling operation [3] is applied. The output of the pooling layer concatenate to a fully-connected layer, while the softmax function is applied on final layer. The model is training using the SGD algorithm with mini-batches set to 64 and learning rate 0.0001.

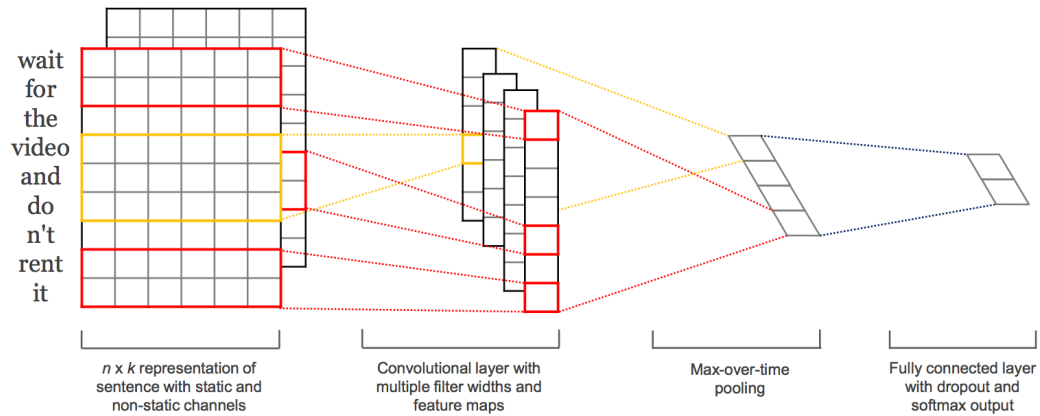

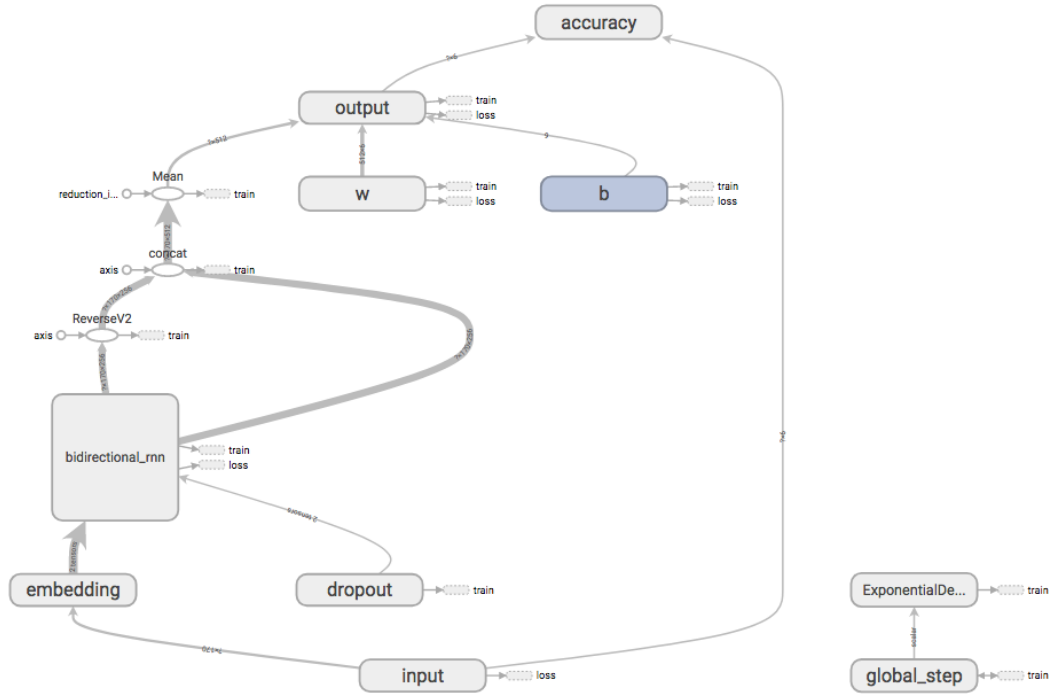

Figure 1: Model architecture with two channels for an example sentence.

BiDirectional Recurrent Neural Networks

Recurrent neural networks (RNN) are networks with loops in them, allowing the persistence of information. A recurrent neural network can be thought of as multiple copies of the same network, each passing a message to a successor. Long Short Term Memory networks, called LSTMs are a special kind of RNN, capable of learning long-term dependencies. All recurrent neural networks have the form of a chain of repeating modules of neural network. In standard RNNs, this repeating module will have a very simple structure, such as a single tanh layer.

The principle of BiDirectional Recurrent Neural Network BRNN is to split the neurons of a regular RNN into two directions, one for positive time direction (forward states), and another for negative time direction (backward states). Those two states output are not connected to inputs of the opposite direction states.

Here I have used a stack Bidirectional LSTM with max k-pooling. The network here has 500 hidden units in the forward and backward LSTM layers. The output of the pooling layer concatenate to a fully-connected layer, while the softmax function is applied on final layer.

VI. RESULTS

A. Logistic Regression

Cross Validation scores from Logistic Regression used a baseline scores:

CV score for class toxic is -0.141080425752
CV score for class severe_toxic is -0.0297990227241
CV score for class obscene is -0.0804189464205
CV score for class threat is -0.0151034029795

CV score for class insult is -0.0895439792452
CV score for class identity_hate is -0.0330330762226
Total CV score is -0.0648298088908

B. CNN

Results from training the CNN for 25 epochs:

Epoch:0 Train Loss: 0.09688197537347747, Train Accuracy: 0.9730627584610475
Epoch:1 Train Loss: 0.044754850838100164, Train Accuracy: 0.9829976767253723
Epoch:2 Train Loss: 0.03855618966644687, Train Accuracy: 0.9851702522504387
Epoch:3 Train Loss: 0.033110798796994634, Train Accuracy: 0.9871704034016947

VII. CONCLUSION

As shown CNN can outperform well established methodologies providing enough evidence that their use is appropriate for toxic comment classification. The promising results are motivating for further development of CNN based methodologies for text mining in the near future, in our interest, employing methods for adaptive learning and providing further comparisons with n-gram based approaches. While a complex BRNN model produced very similar results it can be clearly seen that CNN can be used to produce similar results without the additional disadvantages with RNN's for eg. increased training time.

Additionally the accuracy can be further increased by techniques such as data augmentation and additionally cleaning the input data and normalizing the text.
